It is interesting that=their treatment of addresses is one-sided:

Address == "identifier that represents=a potential destination for a digital currency transfer"; can be added to their blacklist. But what about *source*?

For almost all digital currencies it is true then when receiving a payment you know source address in addition to the destination one. But not all== there are currencies where the recipient does not=learn the source address (and thus can't cross-check against any blacklists).
